

Grad Café entries come from people who choose to post their results, so they are not a random sample of all graduate school applicants. Someone who receives an acceptance, a disappointing rejection, or an unusual decision may be more likely to post than someone with an ordinary result. Some programs and universities may also be more active on the site than others. In my database, **47.92% of Fall 2025 entries are acceptances**, but that is only the percentage of entries submitted to Grad Café. It does not mean that 47.92% of everyone who applied for Fall 2025 was accepted. Applicants who never used the site are missing from this calculation.

The information is also self-reported, and many entries leave out GPA or test scores. People may enter scores incorrectly or use different names for the same program or university. For example, my calculated averages of **259.90 for GRE Quantitative** and **8.34 for GRE Analytical Writing** are implausible, which shows why I should not treat every reported value as reliable. Question 11 found a **0.11 higher average GPA** among accepted than rejected Fall 2026 Computer Science master's entries, but that comparison only includes entries that reported a GPA. Also, Question 9 counted **four more entries** than Question 8 when I used the LLM-generated program and university fields. That difference can come from how names were interpreted; it does not represent four additional admissions. These results describe what is in my database, but they cannot reliably describe every graduate school applicant.
